Chapter 1. Overview

Murano is an Application catalog for Openstack. Full information about Murano in Openstack wiki page. [<https://wiki.openstack.org/wiki/Murano>] Murano Project introduces an application catalog, which allows application developers and cloud administrators to publish various cloud-ready applications in a browsable categorised catalog. It may be used by the cloud users to pick-up the needed applications and services and composes the reliable environments out of them in a “push-the-button” manner. Murano UI is just a plugin to Openstack dashboard - Horizon. Please visit horizon user guide first to see how dashboard is organized and how to log in to it. This document describes Murano Application Catalog usage in detail.

Document change history

The following table describes the most recent changes:

Revision Date	Summary of Changes
September 4, 2013	• Update for Release-0.2
December 9, 2013	• Update for Release-0.4
April 22, 2014	• Update for Release-0.5

Chapter 2. Application Catalog

Environments

Application Catalog Environment - a virtual unit to store different services (applications). They can be connected with each other or be individual. The following actions with environment are available:

- Create;
- Edit;
- Delete;
- Deploy.

More information about actions with environment are described in this chapter.

Creating environment

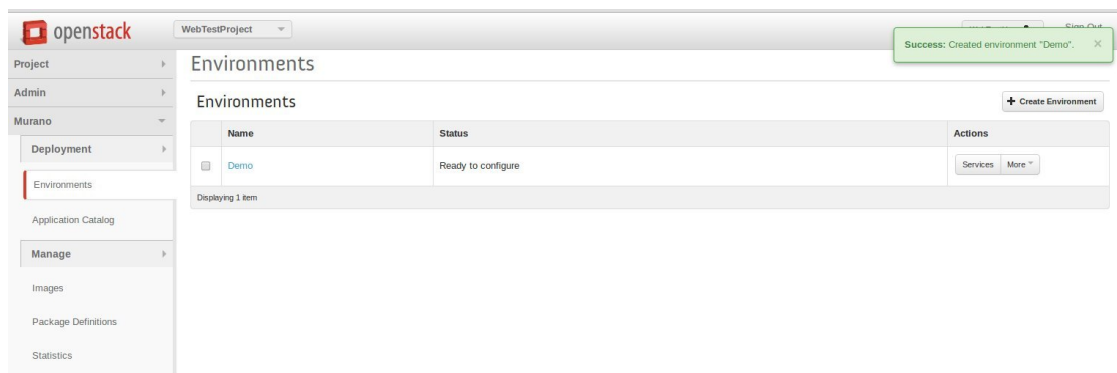

Once you installed all Murano components and logged-in to horizon dashboard successfully you will see Murano tab:

First thing you need to do is to create an environment. To do this, navigate to the Application Catalog > Environments page and click to the "Create Environment". After setting name to your virtual environment it will be created.

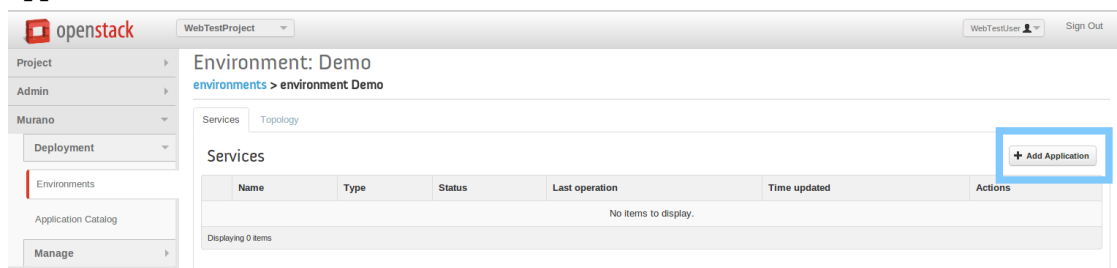

Just created environment has status *Ready to configure*.

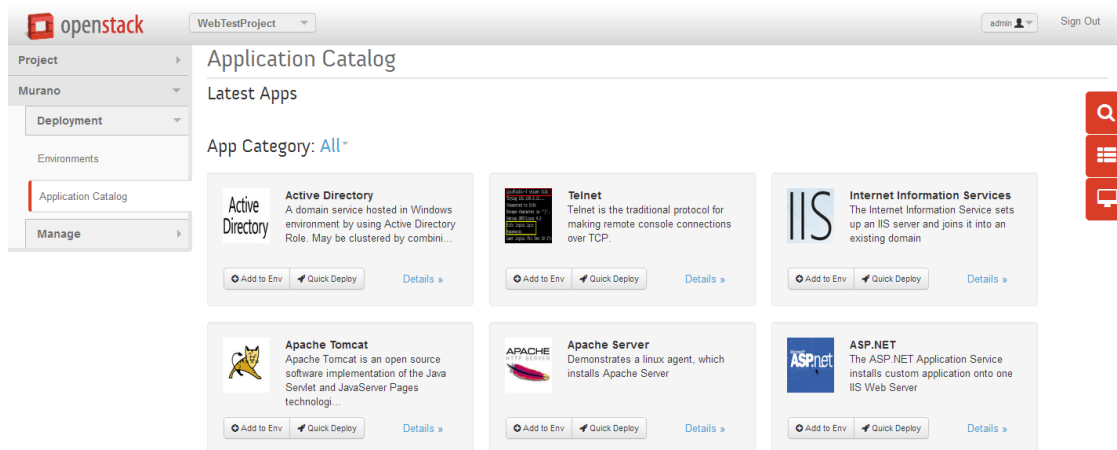

Adding application to the environment

After Environment is created, you need to add applications to this environment and then send the environment to deploy. When deploy process is done instances with your applications will be spawned in OpenStack. To add an application, navigate to the page with the list of environment components by clicking on the environment name (or on the "Components" button) and then, click the "Add Application" button.

After that, you will be redirected to the "Applications" page. Here you can see all applications: tenant applications and public applications. (Information about how to upload your own application package to repository is available in appropriate chapter.) Base Murano public applications are described below.

Once you choose application that you want to add click "Add to Env" and fill the form. Forms for each application are specific. To see more information about filling the form for a specific application follow one of the link below:

- **ASP.NET Application:** is a server-side Web application framework designed for Web development to produce dynamic Web pages. Application is able to install custom services onto one IIS Web Server. Murano installs all needed components and makes proper configuration.
- **ASP.NET Farm Application:** ASP.NET Farm Application installs a custom application on a load-balanced array of IIS servers.
- **Active Directory:** Active Directory is a directory application implemented by Microsoft for Windows domain networks. In one installation, in addition to primary Domain Controller, you can add optional count of secondary Domain Controllers. Any other applications you are intending to create can be joined to that domain.
- **Apache Application:** Apache HTTP Server is a web server application notable for playing a key role in the initial growth of the World Wide Web. This application can install Apache with PHP module or without it.
- **Apache Tomcat:** Apache Tomcat is an open source software implementation of the Java Servlet and JavaServer Pages technologies.
- **Demo Application:** Installs test application that demonstrates how to Murano interconnects with Murano Demo Agent. For this application light-weight Linux Cirros image can be used.
- **Internet Information Application:** IIS is a web server and a set of feature extension modules.
- **Internet Information Web Farm Application:** Murano installs the Web Farm Framework on the controller server, configures the primary server and prepares the secondary servers. In addition load balancer is installed to monitor application statuses.
- **Linux Telnet:** "AD Telnet - is a network protocol used to provide a bidirectional interactive text-oriented communication facility using a virtual terminal connection.
- **MS SQL Application:** Microsoft SQL Application is a relational database management system.
- **MS SQL Server Failover Cluster:** Murano installs all needed components and configures your SQL Server Cluster the way you want.
- **PostgreSQL:** PostgreSQL, often simply "Postgres", is an object-relational database management system with an emphasis on extensibility and standards-compliance.

On the last step of creating application prototype you have opportunity to set the hardware flavor of the instance which will be created - and the image with the operating system, which will be installed on the instance. Also you may select availability zone, if there are more then one in your environment.

Create Service ✕

Instance flavor

m1.medium

Instance image

Windows Server 2012 Standard

Availability zone

nova

Internet Information Services Service

Instance Configuration: Specify some instance parameters on which service would be created.

Instance flavor: Select registered in Openstack flavor. Consider that service performance depends on this parameter.

Instance image: Select valid image for a service. Image should already be prepared and registered in glance.

Availability zone: Select availability zone where service would be installed.

Back

Create

Active Directory

After you picked the Active Directory application you'll see the following form:

Create Service

Domain Name

Instance Count

Account Name

Administrator password

Confirm password

Recovery password

Confirm password

Hostname template

Active Directory Service

Domain Name: Enter a desired name for a new domain. This name should fit to DNS Domain Name requirements: it should contain only A-Z, a-z, 0-9, (.) and (-) and should not end with a dash. DNS server will be automatically set up on each of the Domain Controller instances. Note: Only first 15 characters or characters before first period is used as NetBIOS name.

Instance Count: You can create several Active Directory instances by setting instance number larger than one. One primary Domain Controller and a few secondary DCs will be created.

Passwords: Windows requires strong password for service administration. Your password should have at least one letter in each register, a number and a special character. Password length should be a minimum of 7 characters. Once you forget your password you won't be able to operate the service until recovery password would be entered. So it's better for Recovery and Administrator password to be different.

Hostname template: For your convenience all instance hostnames can be named in the same way. Enter a name and use # character for incrementation. For example, host# turns into host1, host2, etc. Please follow Windows hostname restrictions.

Back

Next

Enter or select values for this fields:

Domain name	Enter a desired name for a new domain. This name should fit to DNS Domain Name requirements: it should contain only A-Z, a-z, 0-9, (.) and (-) and should not end with a dash. DNS server will be automatically set up on each of the Domain Controller instances. Period characters are allowed only when they are used to delimit the components of domain style names. Single-level domain is not appropriate. Note: Only first 15 characters or characters before first period is used as NetBIOS name.
Instance Count	You can create several Active Directory instances by setting instance number larger than one. One primary Domain Controller and a few secondary DCs will be created.
Account Name	You account will have Active Directory administrator rights. So initial value is "Administrator" but you can change it to any name you like.
Administrator password	Windows requires strong password for service administration. Your password should have at least one letter in each register, a number and a special character. Password length should be a minimum of 7 characters.

	Once you forget your password you won't be able to operate the service until recovery password would be entered. So it's better for Recovery and Administrator password to be different.
Confirm password	Password confirmation is required.
Recovery password	Restrictions are the same as for the Administrator password. Please provide password that is different from Administrator. It's not required for form validation though.
Confirm password	Password confirmation is required.

Deploying environment

Once environment has all applications, it can be sent to deploy. Just press the "Deploy This Environment" button.

The screenshot shows the OpenStack Murano web interface. On the left is a sidebar with navigation links: Project, Admin, Murano, Deployment, Environments, Application Catalog, and Manage. The main content area is titled 'Environment: Demo' and shows a list of services. The 'Services' tab is active, displaying a table with columns: Name, Type, Status, Last operation, Time updated, and Actions. Two services are listed: 'postgresql' and 'ApacheTomcat', both with a status of 'Ready to configure'. In the top right corner of the main content area, there are three buttons: '+ Add Application', 'Delete Services', and 'Deploy This Environment'. The 'Deploy This Environment' button is highlighted with a blue box.

Name	Type	Status	Last operation	Time updated	Actions
postgresql	PostgreSQL	Ready to configure	Service draft created	-	Delete Service
ApacheTomcat	Apache Tomcat	Ready to configure	Service draft created	-	Delete Service

And you'll see a message about successful start of deploying your services in Openstack. Since now all you have to do is just wait for a little bit while Murano is installing and configuring your applications.

The screenshot shows the OpenStack Application Catalog interface. The left sidebar contains navigation links: Project, Admin, Murano, Application Catalog, Environments, Applications, Statistics, and Manage. The main content area is titled 'Environment: Demo' and shows a table of components. The table has columns: Name, Type, Status, Last operation, Time updated, and Actions. One component is listed: 'Demo' of type 'PostgreSQL' with status 'Deploy in progress'. The last operation is 'Creating VM for a PostgreSQL app.' and the time updated is '2014-04-28 12:31:53'.

Name	Type	Status	Last operation	Time updated	Actions
Demo	PostgreSQL	Deploy in progress	Creating VM for a PostgreSQL app.	2014-04-28 12:31:53	

You can monitor deploying process. Just go to the Log tab on application detailed page, where you can get by clicking on the application name. And now you can see installation logs.

The screenshot shows the OpenStack Service Detail page for 'demo.com'. The left sidebar contains navigation links: Project, Admin, CURRENT PROJECT Anastasia, Manage Compute (Overview, Instances, Volumes, Images & Snapshots, Access & Security), Other, and Environments. The main content area is titled 'Service Detail: demo.com' and shows a table of service logs. The table has columns: Time, Operation, and Instance. The logs show the creation of an instance and a primary domain controller.

Time	Operation	Instance
2013-09-05 21:29:41	Creating instance ad (demo.com_instance_0)	
2013-09-05 21:29:16	Instance ad (demo.com_instance_0) created	
2013-09-05 21:28:19	Creating Primary Domain Controller on unit ad (demo.com_instance_0)	
2013-09-05 21:44:01	Primary Domain Controller created	

As long as installation and configuration are in progress, environment is in *Deploy in progress* state. Depending on how many applications you are deploying or how many nodes in your cluster, process of spawning instances, installation and post installation settings takes from 10 minutes up to one hour.

The screenshot shows the OpenStack Environments page. The left sidebar contains navigation links: Project, Admin, Murano, Application Catalog, Environments, Applications, Statistics, and Manage. The main content area is titled 'Environments' and shows a table of environments. The table has columns: Name, Status, and Actions. One environment is listed: 'Demo' with status 'Deploy in progress'. The actions column contains links for 'Components' and 'More'.

Name	Status	Actions
Demo	Deploy in progress	Components More

If installation process finished without any errors, environment changes its status to *Ready*:

172.18.79.30/localhost/project/0/environments/environments

Now you are seeing general information about the application in terms of Murano Environment. To get information about the instance in Openstack terms follow the link on application instance name.

Service unit1

Hostname
IIS1

Service instance name
e98a933da40ee4dc096b7f7d7be4fa3de.IIS1

You can log in to the virtual machine directly from the horizon (if your Openstack installation allows you) or by RDP protocol.

There are more things you can do with Murano Environment:

- Add new application and deploy it again;
- Delete outdated and unnecessary environments or applications;
- Browse deployment history and application installation logs;
- Rename your environment.

Redeploy Murano Environment

Murano gives an opportunity to supplement already deployed environment. Thus if you already deployed the Active Directory application and want to add any other applications just create desired application prototype and click the "Deploy This Environment" button. During application prototype creation you can join this application to the existent Active Directory domain.

Delete

Applications as well as environments can be easily deleted.

- To delete an environment go to the Application Catalog > Environments index page and click "More" -> "Delete Environment" in Actions column of ready to delete environment.

Environment deletion means to kill all services with instances on which they are installed. Instances will be scheduled to delete right after you choose the "Delete Environment" action.

- To delete an application go to the application list page and click the "Delete Service" button in Actions column. **Note:** If you are deleting application that was already deployed you'll need to *Deploy* the environment again by pressing corresponding button. In case you want to delete application prototype - it has *"Service draft created"* in the *Last operation* column (see the screenshot below) - changes applies right away.

Browse Murano Deployment

Since Murano Environment can be deployed many times you may want to see the history of its deployments. To do that click the "More-> Show deployments" button on environments index page:

From this page it's easy to see how many times and when Murano Environment was deployed:

For each deployment you can get a detailed information by clicking the "Show Details" button. You always can go back to any level using navigation string at the page header. From here you can observe which applications were installed during deployment:

Also deployment logs are available at the "Logs" tab:

The screenshot shows the OpenStack Dashboard interface. On the left is a sidebar with the OpenStack logo and navigation links: Project, Admin, CURRENT PROJECT Anastasia, Manage Compute (Overview, Instances, Volumes, Images & Snapshots, Access & Security), Other, and Environments. The main content area is titled 'Deployment information' and shows the breadcrumb 'environments > Demo deployments > deployment at 2013-09-06 21:29:35'. It has tabs for 'Configuration' and 'Logs'. The 'Logs' tab is active, displaying a list of deployment events:

```
2013-09-06 21:29:35 - Deployment scheduled
2013-09-06 21:29:39 - Creating instance IIS1 (IISdemo_instance_0)
2013-09-06 21:29:39 - Creating instance IIS2 (IISdemo_instance_1)
2013-09-06 21:29:39 - Creating instance ad (demo.com_instance_0)
2013-09-06 21:29:54 - Instance IIS1 (IISdemo_instance_0) created
2013-09-06 21:29:55 - Instance IIS2 (IISdemo_instance_1) created
2013-09-06 21:29:55 - Instance ad (demo.com_instance_0) created
2013-09-06 21:29:56 - Creating Primary Domain Controller on unit ad (demo.com_instance_0)
2013-09-06 21:45:03 - Primary Domain Controller created
2013-09-06 21:45:09 - Deployment finished
```

Rename Murano Environment

It's possible to change the name of your environment: just click the "More-> Edit Environment" button on environment index page:

The screenshot shows the OpenStack Dashboard 'Environments' page. The sidebar on the left has 'Environments' highlighted. The main content area shows a table with one environment named 'Demo' in 'Ready to configure' status. The 'Actions' column for the 'Demo' row has a 'More' dropdown menu open, showing 'Edit Environment' (highlighted with a blue box) and 'Delete Environment' (in red text). A '+ Create Environment' button is in the top right corner.

Name	Status	Actions
Demo	Ready to configure	Services More Edit Environment Delete Environment

Environment name will correspond with heat stack name. So the name must contain only alphanumeric characters (case sensitive) and - character.

Applications

At the Application Catalog -> Applications page all applications, registered in Application Catalog, are shown.

To see the full description of an application just click on the Details button.

And you will see all information about the application, its requirements and licence. From here you can add application to the current environment by pressing the corresponding button.

If there are more then six applications you can use navigation bar underneath.

Desired application can be easily found with the Search button. It's located on the right side. You can enter any words or digits: applications will be searched by there names, tags, categories or by date of creation or modification.

Applications can be added to the existing environment. To select the environment witch you want to add application just click to the environment selector button.

You can filter applications by categories with category selector. It's located on the top of the page. Click on the desired category name and all applications not related to that category will be hidden.

Chapter 3. Murano Management

Package definitions

Cloud administrator has rights to manage applications in the catalog: upload new applications, modify existing, disable or delete them. All this actions are available in Murano UI and will be described in this section. Go to the *Manage ->Package Definitions* page.

- Upload Package provides a form for uploading an application package. After this operation your application will be acceptable from application catalog.

Upload Package

Application .zip package *

Выберите файл Файл не выбран

Application Category *

Web
Databases
Message Queue
Application Servers

Description:

Choose package archive to upload.

Files could be nested and should not be exist in the server.

Cancel

Upload

You'll need to provide path to the package with your application. It should be in a zip format. See here [https://wiki.openstack.org/wiki/Murano/Documentation/How_to_create_application_package] for more information on how to prepare an application package. Also select one category to which your application belongs too.

- **Toggle Active** makes an application active or disabled depending on the current state.
- **Delete Packages** removes applications from the catalog
- **Modify Package** gives you opportunity to modify meta information about the application.

Description

Description:

Name is a human-readable name of a package.

Categories are a predefined set of values used to filter the packages.

Tags are an arbitrary comma-separated values also used to filter the packages.

Public defines whether or not should be package shown to the other tenants.

Active is used for temporarily disabling a package.

Description consists of several sentences about the package's purpose.

The following properties are allowed to edit:

- **Name** - visible application name
- **Categories** - change application category
- **Tags** - specify comma-separated list of words, associated with the application
- **Public** - indicates access for non-admin users from all tenants
- **Active** - indicates if this application is enabled or disabled
- **Description** - extend information about application, which will be shown at the Application Details page
- **Download Package** saves application definition as zip archive, as it was uploaded

Murano Images

Murano uses preconfigured images for spawning instances. Image suitable for Murano should have Murano Agent installed at least. See [here](http://murano-docs.github.io/latest/administrators-guide/content/ch03.html) [http://murano-docs.github.io/latest/administrators-guide/content/ch03.html] how to build Murano images and upload it to Glance. Since Murano supports different operating systems it's not possible to use one image to build every single application. To classify images

Metadata property of Glance image is used. Murano Dashboard allows to add that property from a separate view. Navigate to the Murano tab and go to Images panel.

Warning

To operate with Glance Images you need to have admin rights!

You are browsing Glance images with correctly set "murano_image_info" property - image metadata. From this view you are able to:

- Delete an existing image metadata with "Delete Metadata" button (only image's property get deleted, the image itself stays in Glance)
- Add new murano metadata to an image that is already registered in Glance by clicking on "Mark Image" button

Take a look at the "Mark Image" form:

Mark Image

Image *

cloud-fedora

Title *

Type *

Generic Linux

Description:

Mark image with specific Murano metadata. Valid image metadata will be added to the selected image so image can be picked during service creation.

Image: Select one of the images registered in the Glance

Title: Image description which will help you to recognize the image during service creation

Type: Pick image type from types supported by Murano

Cancel

Mark

Image	From all images registered in Glance pick one that was created with Murano Image Builder.
Title	Set name for a selected image to recognize it easier during service creation.
Type	For now there are three supported types:

- | |
|--|
| <ul style="list-style-type: none">• Windows Server 2012 - used to build Windows-based applications• Murano Demo - light-weight Linux Cirros image with Murano Demo Agent• Generic Linux - used to build Linux-based applications |
|--|

Chapter 4. Troubleshooting

FQN

How to debug OpenStack Heat?

If you can execute Heat command via console interface - all good. It is the most simple way to check Heat state on the node - just execute CLI command 'heat list'. See more information about Heat in openstack wiki page [<https://wiki.openstack.org/wiki/Heat/TroubleShooting>]

If 'heat list' returns 503 error

It means that OpenStack Heat configuration files contain incorrect credentials. Need to set 'user' = 'heat' and change passwords 'verybadpass' in all configuration files from directory /etc/heat/

If 'heat list' hangs up

Sometimes you can see that 'heat list' hangs up. The root of this problem - connection to the rabbitMQ.

How I can connect to LoadBalancer instance in Server Farms?

First of all you should have KeyPair file 'murano-lb-key'. You can create this file using commands

```
nova keypair-add murano-lb-key > murano-lb-key.priv  
chmod 600 murano-lb-key.priv
```

And after that server farms need to be created with this KeyPair. The second step is to 'how to connect to VM with LoadBalancer':

```
ssh -i murano-lb-key.priv root@10.0.0.3
```

Murano dashboard can not connect to Murano API. How I can fix it?

This problem has two ways to fix: Add string

```
MURANO_API_URL='http://localhost:8082'
```

to the /etc/openstack-dashboard/local_settings (or /etc/openstack-dashboard/local_settings.py - it depends on OpenStack configuration) and after that web server restart is needed. Add keystone endpoints for Murano API

```
keystone service-create --name muranoapi --type murano --description "Murano-API S
keystone endpoint-create --region RegionOne --service-id
--publicurl http://localhost:8082 --internalurl http://localhost:8082 --adminurl h
```

Murano API Service does not work on CentOS 6.x. WebUI can not connect to this service. How to fix this?

The problem in pip lib routes. Need to upgrade this lib and restart Murano API:

```
python-pip install routes --upgrade
initctl stop murano-api
initctl start murano-api
```

Error 'Unexpected state' during the deployment of Web Farms. What the problem?

Sometimes we can see in deployments logs:

```
2013-08-06 09:10:07 - Unable to deploy instance ipkrmhk0vzq4b6 (asp-farm_instance_
2013-08-06 09:10:07 - Unable to create a Server Farm load balancer on unit ipkrmhk
```

The root of this problem is incorrect configuration - Heat can not create Load Balancer instance. Please, remember that you should have admin access for the project in OpenStack to deploy LoadBalancer and also, you should have KeyPair with default name 'murano-lb-key'.

Error in Murano API logs 'No module named helpers.token_sanitizer'

This pip version problem. Need to install pip 1.4 and after that reinstall murano-client, murano-common and murano-api.
